

# Link layer, LANs: outline

5.1 introduction, services

5.2 error detection,  
correction

5.3 multiple access  
protocols

## 5.4 LANs

- addressing, ARP
- Ethernet
- switches
- VLANs

5.5 link virtualization:  
MPLS

5.6 data center  
networking

5.7 a day in the life of a  
web request

# Ethernet switch

- ❖ *link-layer device: takes an active role*
  - store, forward Ethernet frames
  - examine incoming frame's MAC address, *selectively* forward frame to one-or-more outgoing links when frame is to be forwarded on segment, uses CSMA/CD to access segment
- ❖ *transparent*
  - hosts are unaware of presence of switches
- ❖ *plug-and-play, self-learning*
  - switches do not need to be configured

# Switch: *multiple* simultaneous transmissions

- ❖ hosts have dedicated, direct connection to switch
- ❖ switches buffer packets
- ❖ Ethernet protocol used on *each* incoming link, but no collisions; full duplex
  - each link is its own collision domain
- ❖ *switching*: A-to-A' and B-to-B' can transmit simultaneously, without collisions

*switch with six interfaces  
(1,2,3,4,5,6)*

# Switch forwarding table

Q: how does switch know A' reachable via interface 4, B' reachable via interface 5?

❖ A: each switch has a **switch table**, each entry:

- (MAC address of host, interface to reach host, time stamp)
- looks like a routing table!

Q: how are entries created, maintained in switch table?

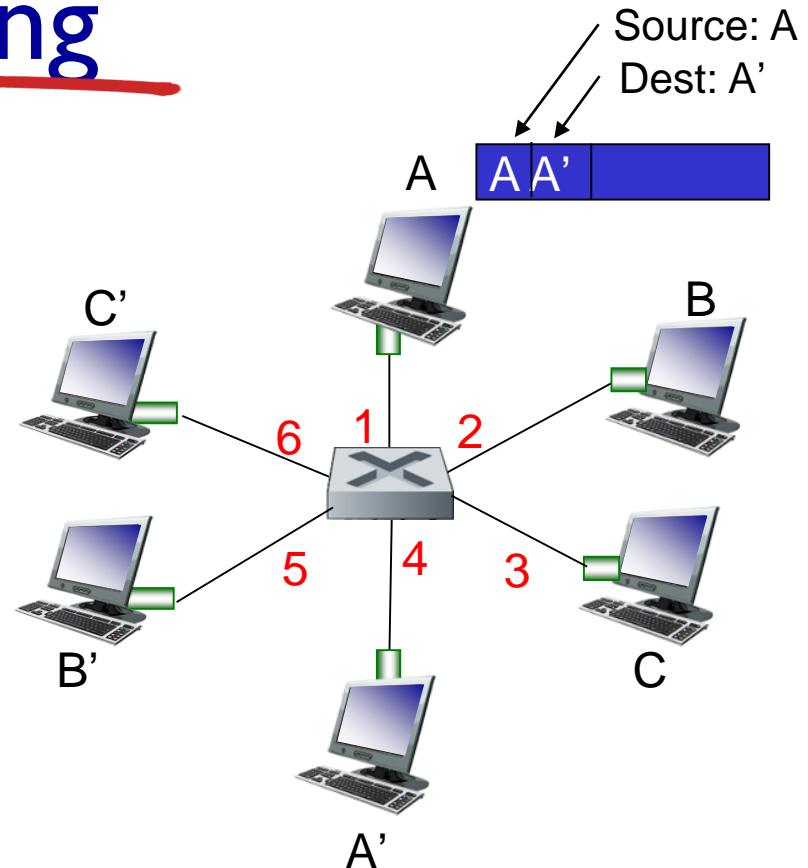

- something like a routing protocol?

switch with six interfaces  
(1,2,3,4,5,6)

# Switch: self-learning

- ❖ switch *learns* which hosts can be reached through which interfaces
  - (only) when frame received, switch “learns” location of sender’s incoming LAN segment
  - records sender/location pair in switch table

*Remember: no ACKs  
when sending Ethernet  
frames!*

| MAC addr | interface | TTL |
|----------|-----------|-----|
| A        | 1         | 60  |
|          |           |     |
|          |           |     |
|          |           |     |

*Switch table  
(initially empty)*

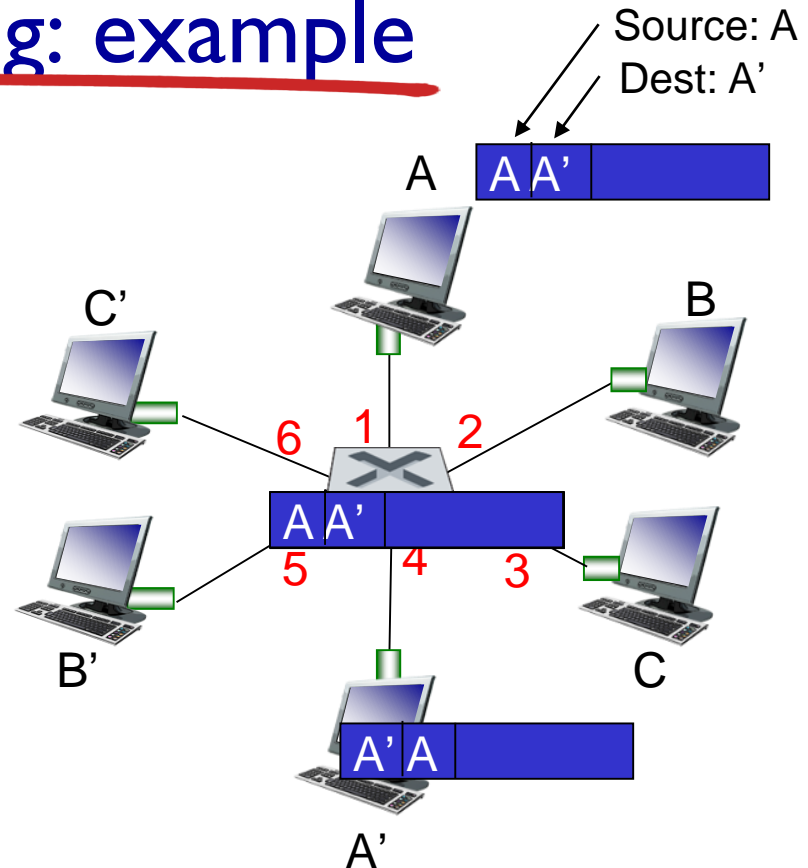

# Switch: frame filtering/forwarding

when frame received at switch:

1. record incoming link, MAC address of sending host
2. index switch table using MAC destination address
3. if entry found for destination, then
  - {
    - if destination on segment from which frame arrived  
then drop frame
    - else  
forward frame on interface indicated by entry
  - }
- else flood // forward on all interfaces except arriving one

# Self-learning, forwarding: example

- ❖ frame destination, A', location unknown: *flood*
- ❖ destination A location known: *selectively send on just one link*

| MAC addr | interface | TTL |
|----------|-----------|-----|
| A        | 1         | 60  |
| A'       | 4         | 60  |

*switch table  
(initially empty)*

# Interconnecting switches

- ❖ switches can be connected together

Q: sending from A to G - how does S<sub>1</sub> know to forward frame destined to G via S<sub>4</sub> and S<sub>3</sub>?

- ❖ A: self learning! (works *exactly* the same as in single-switch case!)

# Self-learning multi-switch example

Suppose C sends frame to I, I responds to C

- ❖ Q: show switch tables and packet forwarding in S<sub>1</sub>, S<sub>2</sub>, S<sub>3</sub>, S<sub>4</sub>

# Institutional network

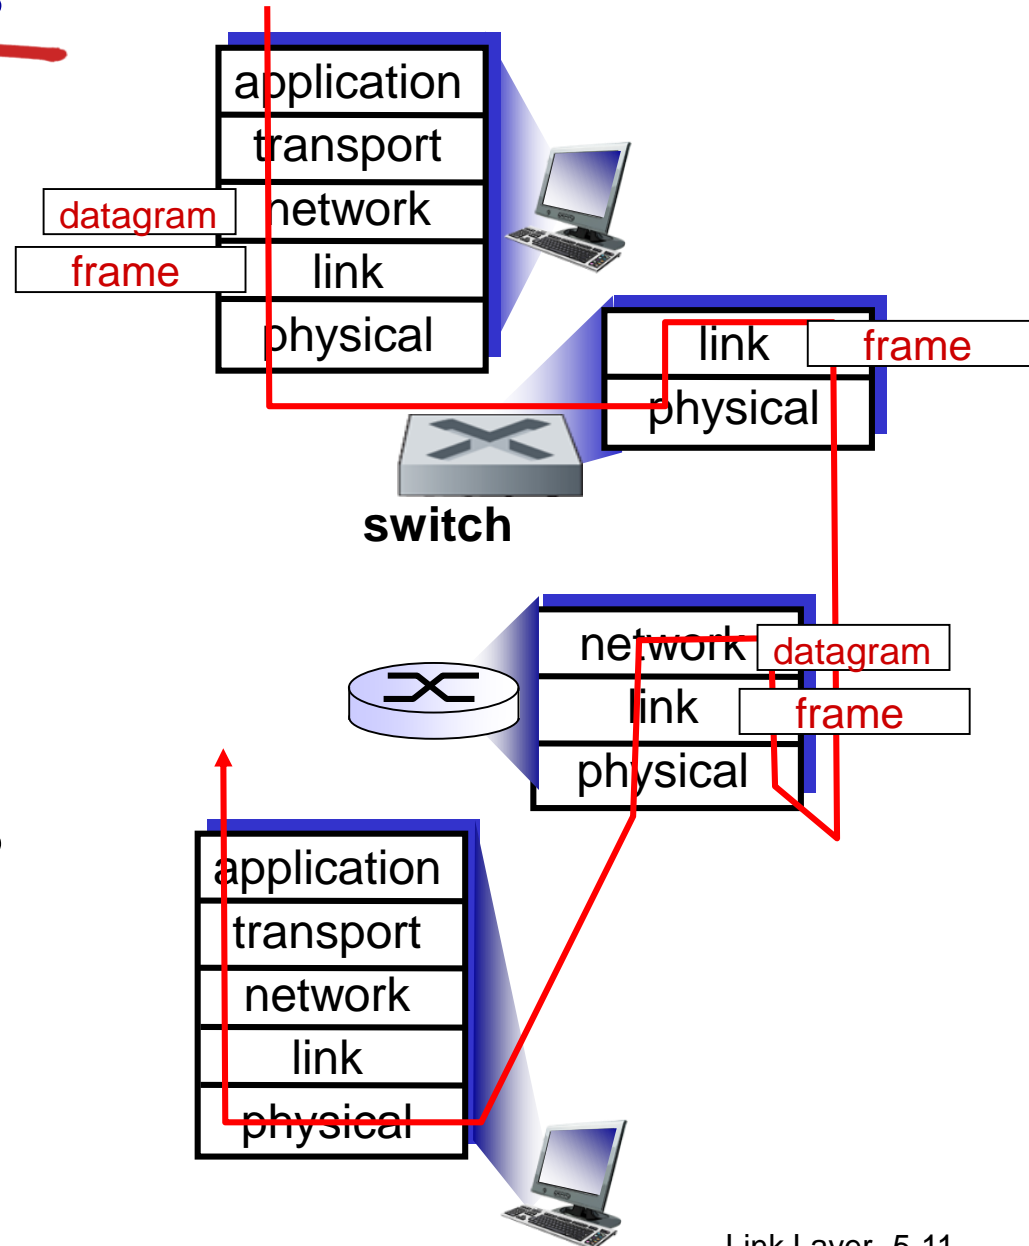

# Switches vs. routers

both are store-and-forward:

- **routers:** network-layer devices (examine network-layer headers)
- **switches:** link-layer devices (examine link-layer headers)

both have forwarding tables:

- **routers:** compute tables using routing algorithms, IP addresses
- **switches:** learn forwarding table using flooding, learning, MAC addresses

# VLANs: motivation

## *consider:*

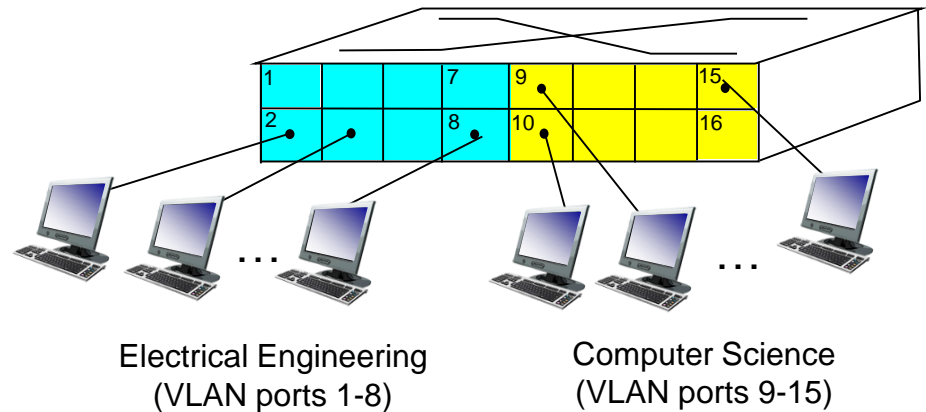

- ❖ CS user moves office to EE, but wants connect to CS switch?
- ❖ single broadcast domain:
  - all layer-2 broadcast traffic (ARP, DHCP, unknown location of destination MAC address) must cross entire LAN
  - security/privacy, efficiency issues

# VLANs

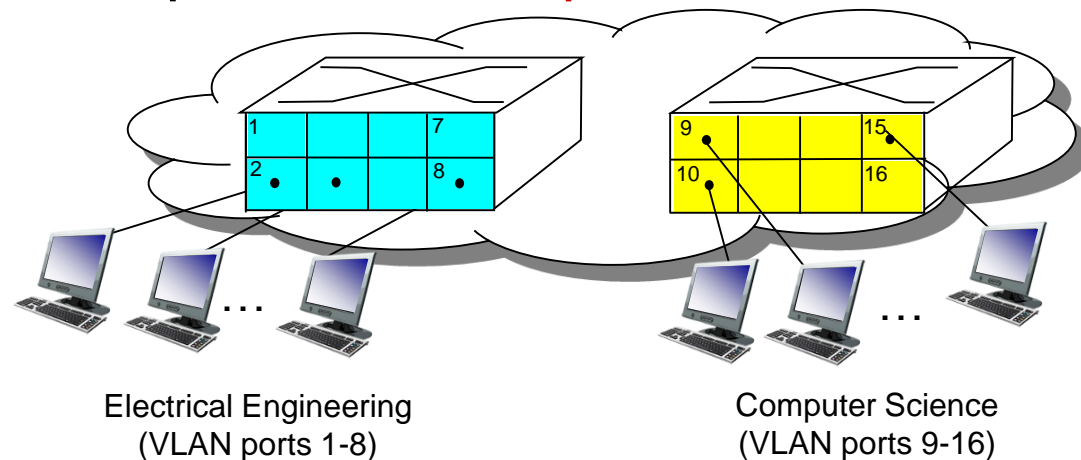

## *Virtual Local Area Network*

switch(es) supporting VLAN capabilities can be configured to define multiple *virtual* LANS over single physical LAN infrastructure.

**port-based VLAN:** switch ports grouped (by switch management software) so that *single* physical switch .....

... operates as *multiple* virtual switches

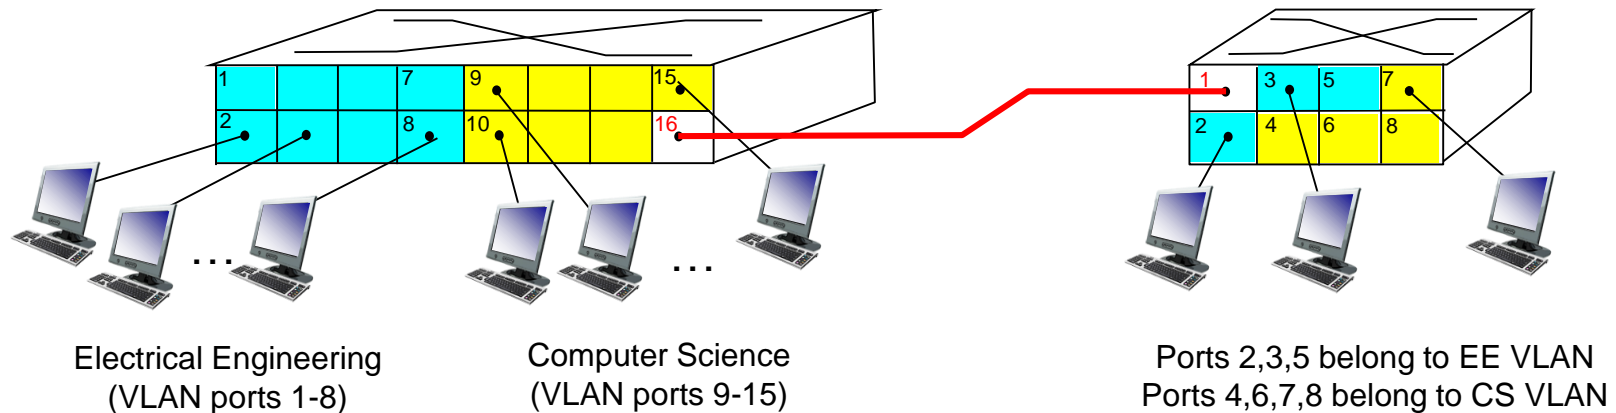

# Port-based VLAN

- ❖ *traffic isolation*: frames to/from ports 1-8 can *only* reach ports 1-8
  - can also define VLAN based on MAC addresses of endpoints, rather than switch port
- ❖ *dynamic membership*: ports can be dynamically assigned among VLANs
- ❖ *forwarding between VLANs*: done via routing (just as with separate switches)
  - in practice vendors sell combined switches+routers

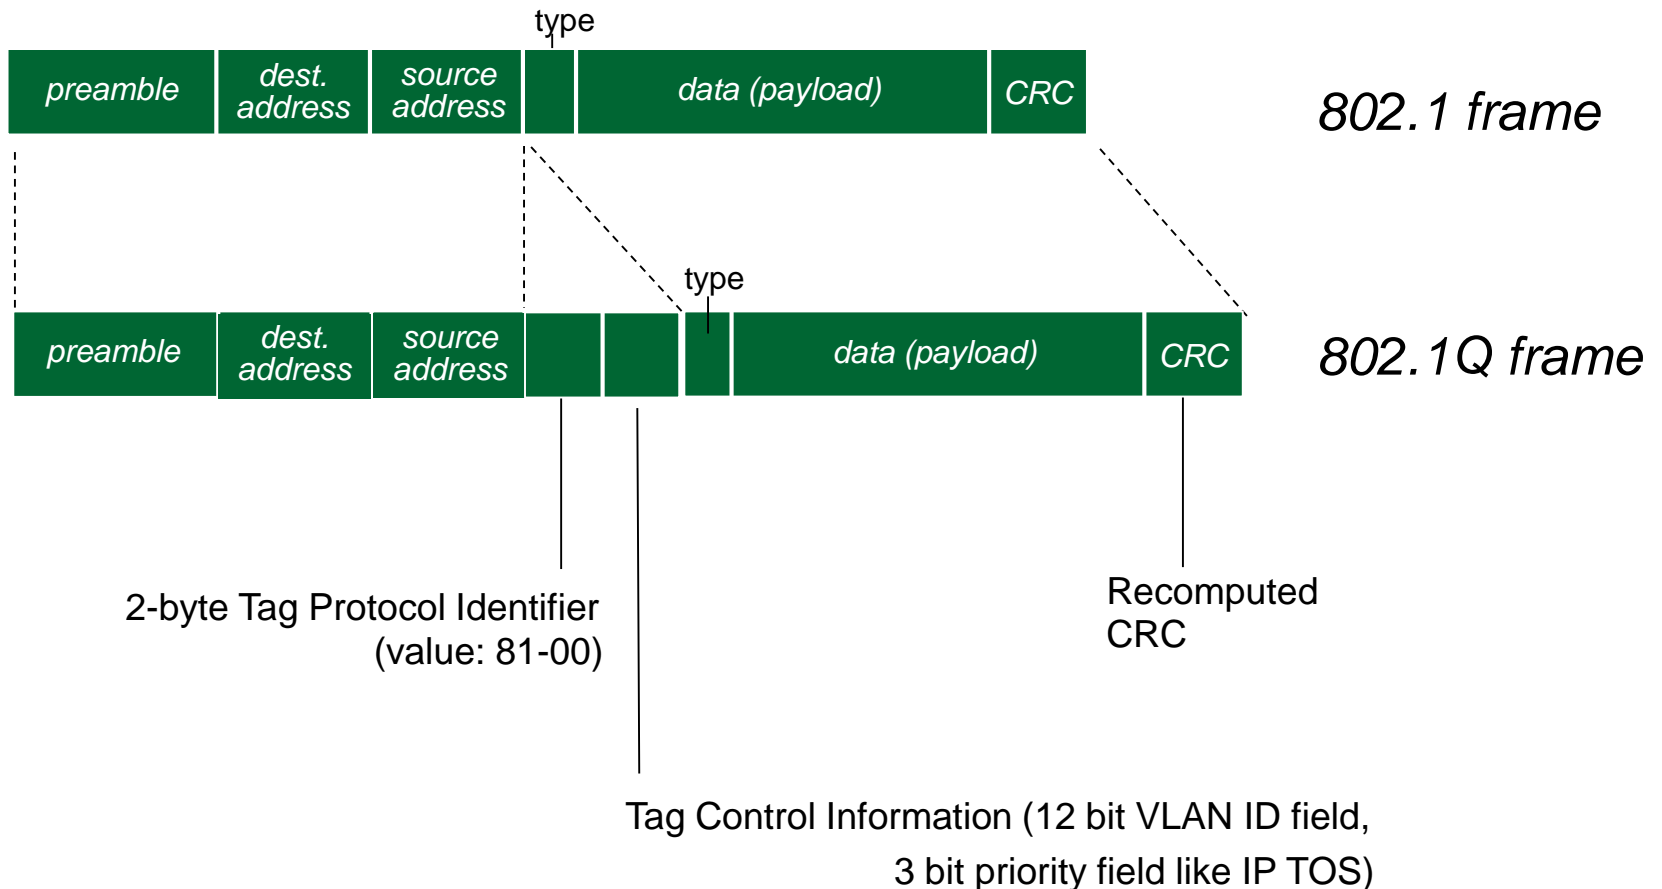

# VLANs spanning multiple switches

- ❖ **trunk port:** carries frames between VLANs defined over multiple physical switches
  - frames forwarded within VLAN between switches can't be vanilla 802.1 frames (must carry VLAN ID info)
  - 802.1q protocol adds/removes additional header fields for frames forwarded between trunk ports

# 802.1q VLAN frame format
