opencl.pptx

mjb - February 19, 2015

OpenCL

- Consists of two parts: a C/C++-callable API and a C-ish programming language. It was originally proposed by Apple, but now is a multi-vendor standard
- The programming language can run on NVIDIA GPUs, AMD GPUs, Intel CPUs, Intel GPUs, and (supposedly) FPGAs. But, OpenCL is at its best on compute devices with large amounts of **data parallelism**, which usually implies GPUs.
- You break your computational problem up into small pieces. Each piece gets farmed out to threads on the GPU in a SPMD way.
- OpenCL can share data, and interoperate with, OpenGL
- There is a JavaScript implementation of OpenCL, called WebCL
- There is a JavaScript implementation of OpenGL, called WebGL
- · WebCL can share data, and interoperate with, WebGL
- The OpenCL C-ish programming language cannot do recursion, cannot use pointers, and cannot use a stack.

Who Is Behind OpenCL? Members of Khronos's OpenCL Working Group

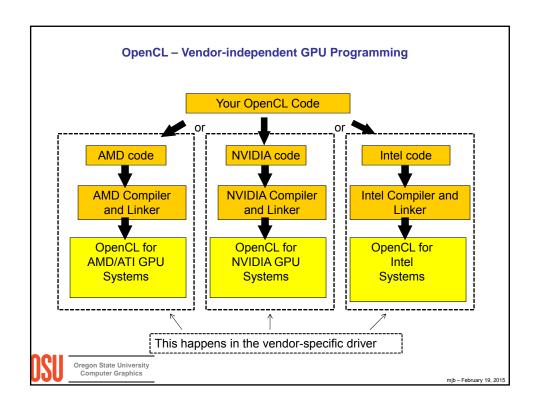

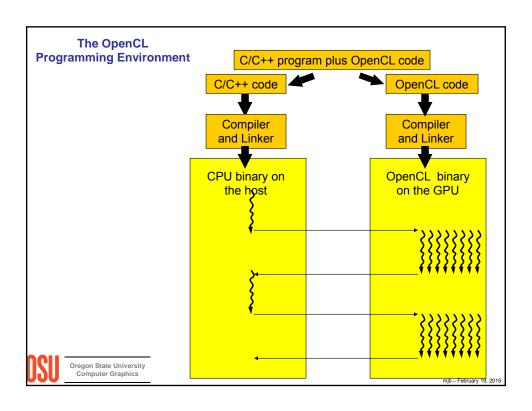

mjb – February 19, 2015

Example of using OpenCL in a System-on-a-Chip: Qualcomm Node – Full Linux and OpenCL

OpenCL wants you to break the problem up into Pieces

```
If you were writing in C/C++, you would say:
```

If you were writing in OpenCL, you would say:

```
kernel
void
ArrayMult( global float *dA, global float *dB, global float *dC)
{
    int gid = get_global_id ( 0 );
    dC[gid] = dA[gid] * dB[gid];
}
```

This is basically PCAM with lots of P and little A

mjb – February 19, 2015

The OpenCL Language also supports Vector Parallelism

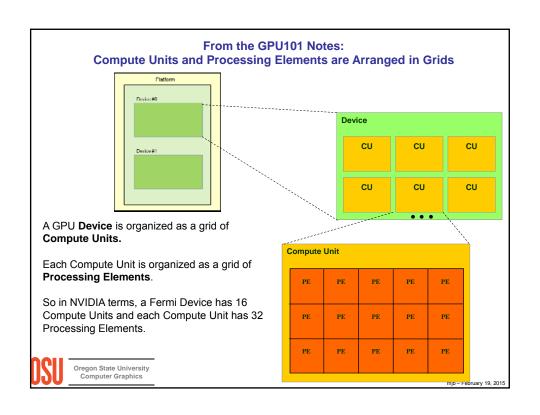

OpenCL code can be vector-oriented, meaning that it can perform a single instruction on multiple data values at the same time (SIMD).

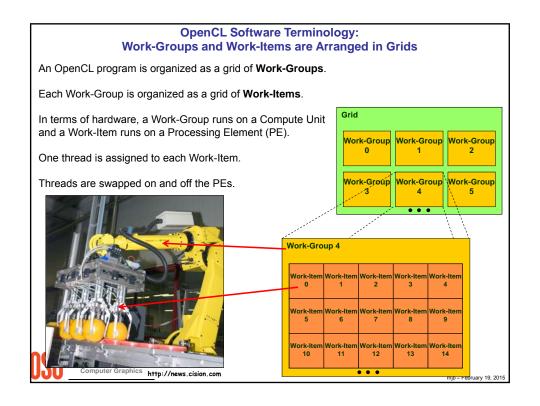

Vector data types are: charn, intn, floatn, where n = 2, 4, 8, or 16.

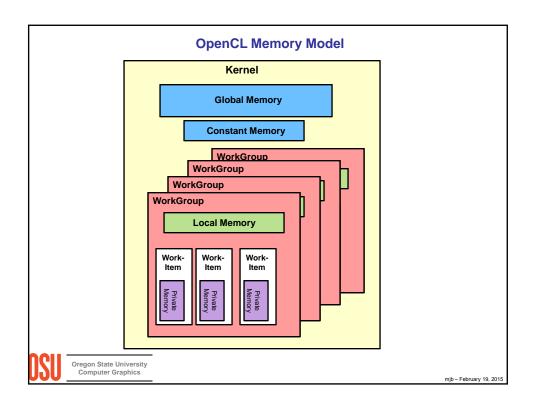

```
float4 f, g;
f = (float4)( 1.f, 2.f, 3.f, 4.f );
float16 a16, x16, y16, z16;
f.x = 0.;
f.xy = g.zw;
x16.s89ab = f;
float16 a16 = x16 * y16 + z16;
```

(Note: just because the language supports it, doesn't mean the hardware does.)

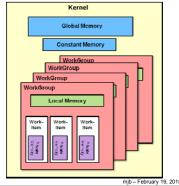

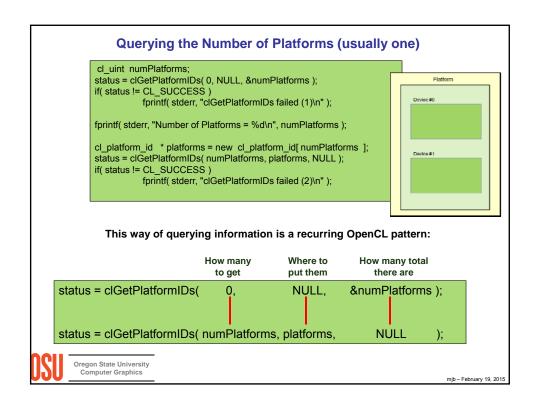

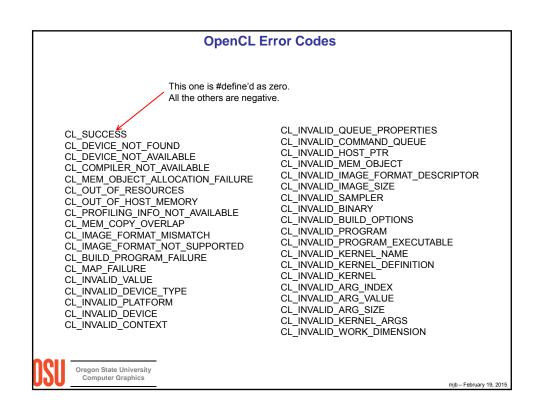

Rules

- Threads can share memory with the other Threads in the same Work-Group
- Threads can synchronize with other Threads in the same Work-Group
- Global and Constant memory is accessible by all Threads in all Work-Groups
- Global and Constant memory is often cached inside a Work-Group
- Each Thread has registers and private memory
- Each Work-Group has a maximum number of registers it can use. These are divided equally among all its Threads

```

Typical Values from Querying the Device

```
Number of Platforms = 1
Platform #0:
          Name = 'NVIDIA CUDA'
          Vendor = 'NVIDIA Corporation'
          Version = 'OpenCL 1.1 CUDA 4.1.1'
          Profile = 'FULL_PROFILE'
          Device #0:
                     Type = 0x0004 = CL_DEVICE_TYPE_GPU
                     Device Vendor ID = 0x10de
                     Device Maximum Compute Units = 15
                     Device Maximum Work Item Dimensions = 3
                     Device Maximum Work Item Sizes = 1024 x 1024 x 64
                     Device Maximum Work Group Size = 1024
                     Device Maximum Clock Frequency = 1401 MHz
                     Kernel Maximum Work Group Size = 1024
                     Kernel Compile Work Group Size = 0 x 0 x 0
                     Kernel Local Memory Size = 0
```

Querying to see what extensions are supported on this device

Steps in Creating and Running an OpenCL program

- 1. Program header
- 2. Allocate the host memory buffers
- 3. Create an OpenCL context
- 4. Create an OpenCL command queue
- 5. Allocate the device memory buffers
- 6. Write the data from the host buffers to the device buffers
- 7. Read the kernel code from a file
- 8. Compile and link the kernel code
- 9. Create the kernel object
- 10. Setup the arguments to the kernel object
- 11. Enqueue the kernel object for execution
- 12. Read the results buffer back from the device to the host
- 13. Clean everything up

mjb – February 19, 2015

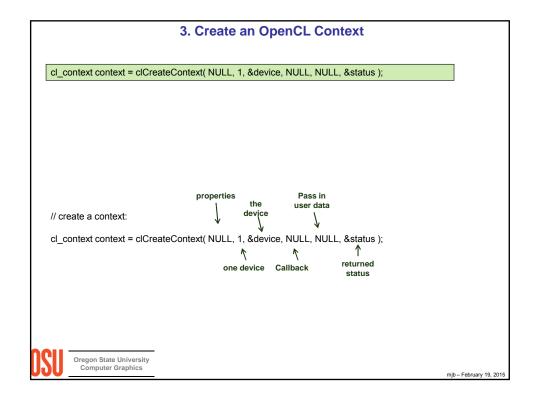

1. .cpp Program Header

#include <stdio.h>
#include <math.h>
#include <string.h>
#include <stdlib.h>
#include <omp.h> // for timing

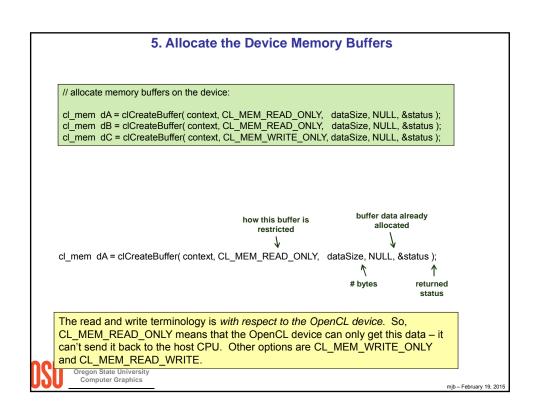

#include "cl.h"

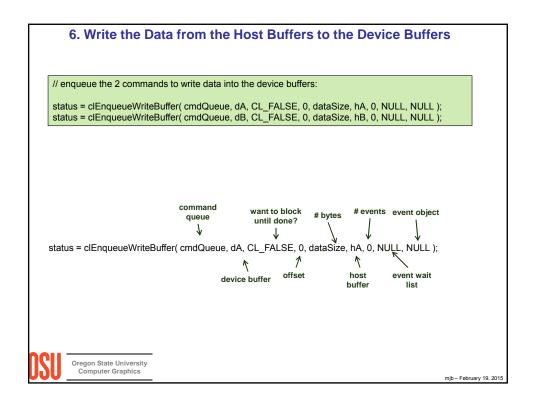

Oregon State University Computer Graphics

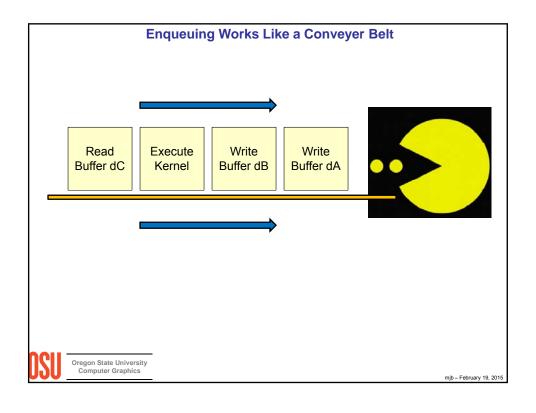

```
2. Allocate the Host Memory Buffers
                                                           This could have also been done like this:
// allocate the host memory buffers:
                                                                       float hA[ NUM_ELEMENTS ];
float * hA = new float [ NUM_ELEMENTS ];
float * hB = new float [ NUM_ELEMENTS ];
float * hC = new float [ NUM_ELEMENTS ];
                                                           Global memory and the heap typically have more space than the stack. So, rarely do you want to allocate large
                                                           arrays like this as a local variable.
                                                           (Here, it's being done on the heap.)
// fill the host memory buffers:
for( int i = 0; i < NUM\_ELEMENTS; i++)
              hA[i] = hB[i] = sqrtf((float)i);
// array size in bytes (will need this later):
size_t dataSize = NUM_ELEMENTS * sizeof( float );
// opencl function return status:
cl_int status;
                                          // test against CL_SUCCESS
      Oregon State University
Computer Graphics
                                                                                                                    mjb – February 19, 2015
```

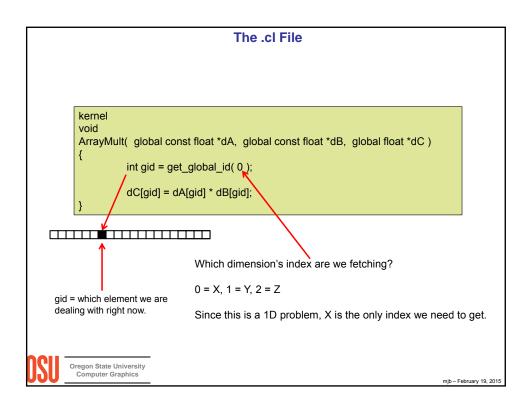

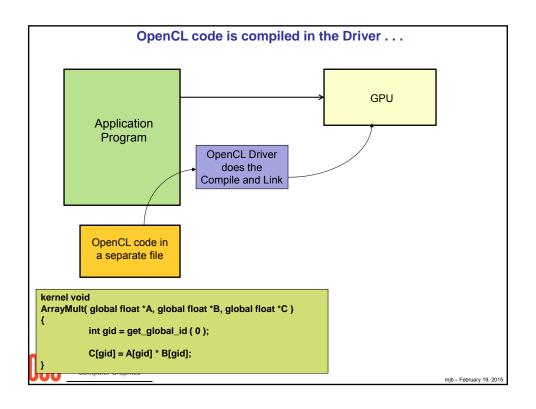

A. Create an OpenCL Command Queue ## Create a command queue: | cl_command_queue cmdQueue = clCreateCommandQueue(context, device, 0, &status); | cl_command_q

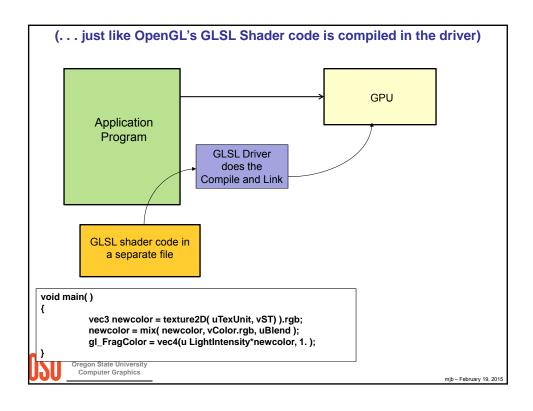

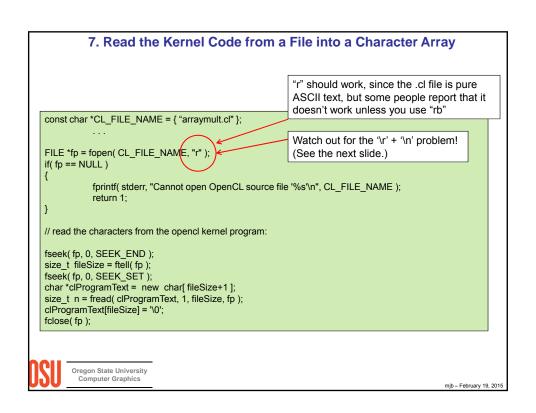

A Warning about Editing on Windows and Running on Linux

Some of you will end up having strange, unexplainable problems with your csh scripts, .cpp programs, or .cl programs. This could be because you are typing your code in on Windows (using Notepad or Wordpad or Word) and then running it on Linux. Windows likes to insert an extra carriage return ('\r') at the end of each line, which Linux interprets as a garbage character.

You can test this by typing the Linux command:

od -c loop.csh

which will show you all the characters, even the '\r' (which you don't want) and the '\n' (newlines, which you do want).

To get rid of the carriage returns, enter the Linux command:

Then run loop1.csh

Or, on some systems, there is a utility called dos2unix which does this for you:

dos2unix < loop.csh > loop1.csh

Sorry about this. Unfortunately, this is a fact of life when you mix Windows and Linux.

mjb - February 19, 2015

8. Compile and Link the Kernel Code

```
// create the kernel program on the device:
char * strings [ 1 ];
                                  // an array of strings
strings[0] = clProgramText;
cl_program program = clCreateProgramWithSource( context, 1, (const char **)strings, NULL, &status );
delete [] clProgramText;
// build the kernel program on the device:
status = clBuildProgram( program, 1, &device, options, NULL, NULL );
if( status != CL SUCCESS )
                                  // retrieve and print the error messages:
           size_t size;
           clGetProgramBuildInfo( program, devices[0], CL_PROGRAM_BUILD_LOG, 0, NULL, &size );
           cl_char *log = new cl_char[ size ];
           clGetProgramBuildInfo( program, devices[0], CL_PROGRAM_BUILD_LOG, size, log, NULL );
           fprintf( stderr, "clBuildProgram failed:\n%s\n", log );
           delete [] log;
```

How does that array-of-strings thing actually work?

```
char *ArrayOfStrings[3];
ArrayOfStrings[0] = ...one commonly-used function...";
ArrayofStrings[1] = " ... another commonly-used function... ";
ArrayofStrings[2] = " ... the real OpenCL code ... ";
cl_program program = clCreateProgramWithSource( context, 1, (const char **) ArrayOfStrings, NULL, &status );
```

These are two ways to provide a single character buffer:

```
char *buffer[1];
buffer[0] = " . . . the entire OpenCL code . . . ";
cl_program program = clCreateProgramWithSource( context, 1, (const char **) buffer, NULL, &status );
```

```
char *buffer = " . . . the entire OpenCL code . . . "; cl_program program = clCreateProgramWithSource( context, 1, (const char **) &buffer, NULL, &status );
```

mjb – February 19, 2015

Why use an array of strings to hold the OpenCL program, instead of just a single string?

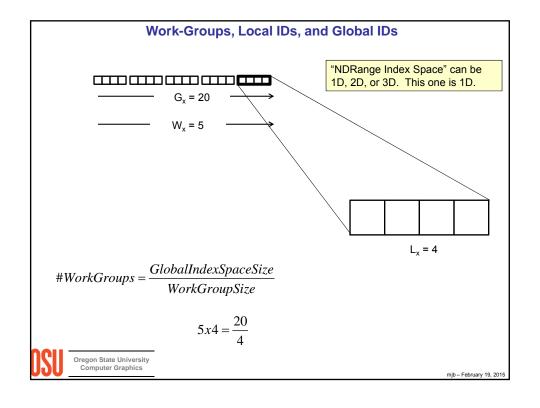

- 1. You can use the same OpenCL source and insert the appropriate "#defines" at the beginning
- 2. You can insert a common header file (≈ a .h file)
- 3. You can simulate a "#include" to re-use common pieces of code

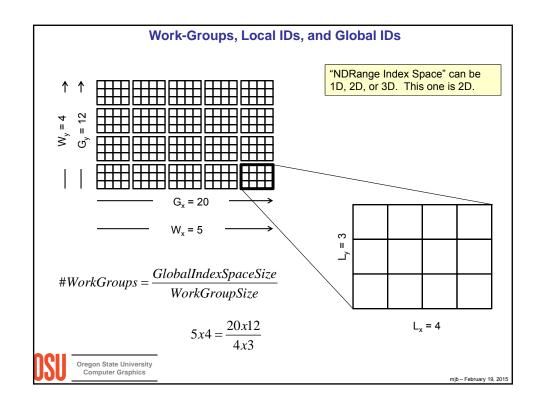

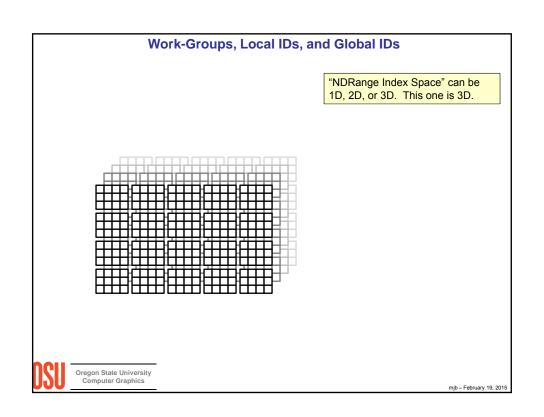

9. Create the Kernel Object cl_kernel kernel = clCreateKernel(program, "ArrayMult", &status); Oregon State University Computer Graphics

status = clSetKernelArg(kernel, 0, sizeof(cl_mem), &dA); status = clSetKernelArg(kernel, 1, sizeof(cl_mem), &dB); status = clSetKernelArg(kernel, 2, sizeof(cl_mem), &dC); Oregon State University Computer Graphics Oregon State University Computer Graphics

11. Enqueue the Kernel Object for Execution size_t globalWorkSize[3] = { NUM_ELEMENT, 1, 1 }; size_t localWorkSize[3] = { LOCAL_SIZE, 1, 1 }; status = clEnqueueBarrier(cmdQueue); double time0 = omp_get_wtime(); status = clEnqueueNDRangeKernel(cmdQueue, kernel, 1, NULL, globalWorkSize, localWorkSize, 0, NULL, NULL); status = clEnqueueBarrier(cmdQueue); double time1 = omp_get_wtime(); # dimensions # event object # dimensions # event object global work offset (always NULL) Oregon State University Computer Graphics

Figuring Out What Thread You Are get_work_dim(); uint get_global_size(uint dimindx) ; size t size t get_global_id(uint dimindx) ; size_t get_local_size(uint dimindx); get_local_id(uint dimindx) ; size_t get_num_groups(uint dimindx); size_t get_group_id(uint dimindx) ; size t get_global_offset(uint dimindx) ; size t $0 \le dimindx \le 2$

mjb – February 19, 2015

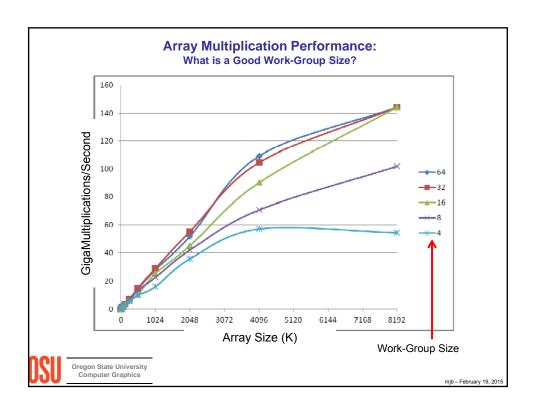

Oregon State University Computer Graphics

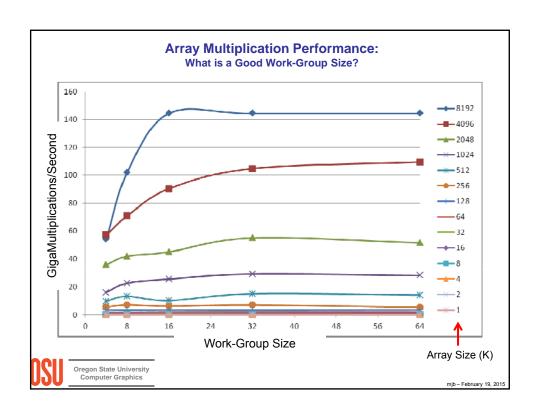

12. Read the Results Buffer Back from the Device to the Host status = clEnqueueReadBuffer(cmdQueue, dC, CL_TRUE, 0, dataSize, hC, 0, NULL, NULL); command want to block # events event object # bytes status = clEnqueueReadBuffer(cmdQueue, dC, CL_TRUE, 0, dataSize, hC, 0, NULL, NULL); 1 offset host event wait device buffer buffer list Oregon State University Computer Graphics mjb – February 19, 2015

```
// clean everything up:

clReleaseKernel( kernel );
clReleaseProgram( program );
clReleaseMemObject( dA );
clReleaseMemObject( dB );
clReleaseMemObject( dC );
delete [ ] hA;
delete [ ] hB;
delete [ ] hC;

Oregon State University
Computer Graphics
```

writing the .cl Program's Binary Code size_t binary_sizes; status = clGetProgramInfo(Program, CL_PROGRAM_BINARY_SIZES, 0, NULL, &binary_sizes); size_t size; status = clGetProgramInfo(Program, CL_PROGRAM_BINARY_SIZES, sizeof(size_t), &size, NULL); unsigned char *binary = new unsigned char [size]; status = clGetProgramInfo(Program, CL_PROGRAM_BINARIES, size, &binary, NULL); FILE *fpbin = fopen("particles.nv", "wb"); if(fpbin == NULL) { fprintf(stderr, "Cannot create 'particles.bin'\n"); } else { fwrite(binary, 1, size, fpbin); fclose(fpbin); } delete [] binary;

Importing that Binary Code back In:

8. Compile and Link the Kernel Code

Instead of doing this:

```
char * strings [ 1 ];
strings[0] = clProgramText;
cl_program program = clCreateProgramWithSource( context, 1, (const char **)strings, NULL, &status );
delete [ ] clProgramText;
```

You would do this:

unsigned char byteArray[numBytes];
cl_program program = clCreateProgramWithBinary(context, 1, &device, &numBytes, &byteArray, &binaryStatus, &status);
delete [] byteArray;

And you still have to do this:
